The pulmonary delivery of proinflammatory oxidized phospholipids (OxPLs) such as 3-deoxyphosphorylcholine (PC) and oxidized phosphatidylcholine (OxPC) may be involved in the etiology of chronic obstructive pulmonary disease (COPD). Thus, we investigated the delivery and deposition of PC and OxPC into the alveolar space using alveolar lavage (ALV) and blood as the primary routes of exposure. 2-deoxy-PC and 2-deoxy-PC-2H4 are structurally different molecular probes for OxPLs because they are more stable than PC and OxPC due to the absence of a double bond at C2 of the choline head group, which makes these probes less prone to degradation. Although 2-deoxy-PC was significantly more soluble in the media than PC or OxPC (at pH 4.5), PC and OxPC were the predominant forms of OxPL in BAL and plasma after 4-h incubation. The pulmonary delivery of PC, OxPC, and OxPL was significantly greater in the PAH-susceptible F344 rat than in the resistant Lewis rat, and significant positive associations between lung OxPL levels and emphysema development in a chronic smoke exposure model were observed. The greater delivery of PC, OxPC, and OxPL to the lung in the F344 rat may be due to genetic ce6e30c18e
